

Bald Eagle: day-resolved response around spawn onset

Each point is (near - reference) on that day minus the same difference in the registered baseline, days -28 to -15. Near is within 5 km. Filled markers mark intervals excluding 1. The pooled registered contrast gives 1.164 for reported number and 1.119 for reporting, because it weights days 4 to 14 at eleven fifteenths against days 0 to 3 at four fifteenths.

Exploratory. One species, chosen after the family results were known. No Benjamini-Hochberg family, and no multiplicity adjustment across the eleven days, which are not independent. Event-block random intercept only, so these intervals are Stage 2 width: narrower than a block-aware interval by roughly the 16 to 18 per cent median widening measured in `post_stage4a_blockaware_v1`. Reporting $n = 217,199$ (Wald), reported number $n = 83,359$ (Satterthwaite denominator). Source: `outputs/post_stage4a_event_time_v1/`.
